

# IN4MATX 133: User Interface Software

Lecture:  
Separation in Angular

# Announcements

## A Couple of Updates

- Due dates for remaining assignments have been bumped back by two days. So instead of a Monday due date, you will now have a Wednesday due date.
- Extra credit opportunity 1 (opp 2 will be announced week 8)
  - Earn an additional 1 pt on your overall grade
  - Help work on a research project for your TA Stella Lau
  - Two options:
    - Option 1: Use a custom GPS device while you move around campus on your scooter (must have a scooter!)
    - Option 2: Create a visualization using the data collected by Option 1
- If interested, Stella will announce sign up information on Zulip

# Today's goals

**By the end of today, you should be able to...**

- Differentiate and explain the roles of Angular components, modules, and services
- Implement a service in Angular
- Navigate Angular's file structure

# But first...

## Let's talk about ngModel

To refresh...

# Two-way binding [( )]

- “You often want to both display a data property and update that property when the user makes changes”
- Most common use: binding to user-generated input
- ngModel directive enables two-way binding to input fields

`<!--enteredText variable contains inputted text-->`

`<!--textChanged() is called after every keystroke-->`

`<input [(ngModel)]="enteredText" (change)="textChanged()">`

<https://angular.io/guide/template-syntax>

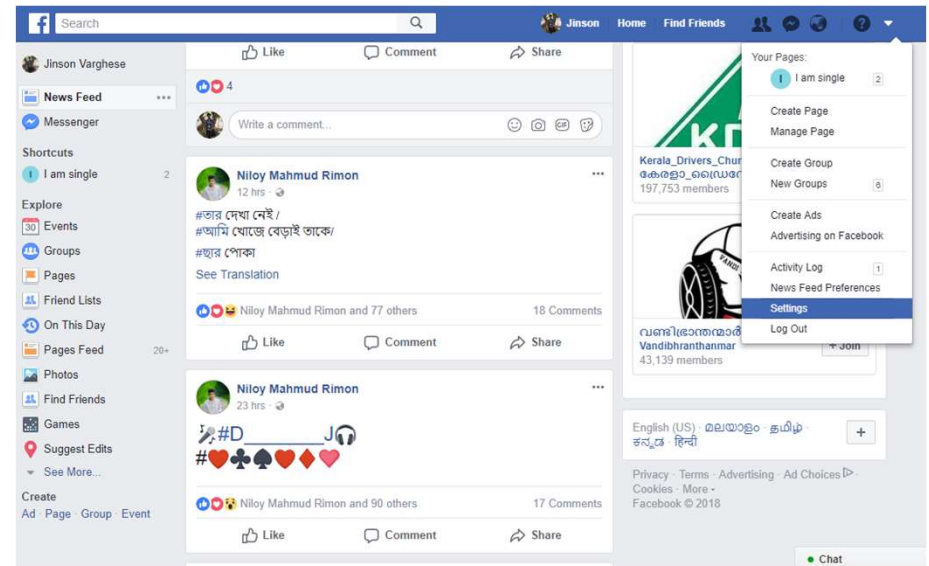

# But first...

## Let's talk about ngModel

- ngModel has been deprecated for use in *reactive forms*
- ngModel has not been deprecated as it's used in assignment 3
- Assignment 3 uses *template-driven* forms
- ngModel was deprecated in reactive forms b/c it behaved differently than the ngModel in template forms...which was confusing.

# A “large” client interface

- Hundreds of pages and ways to navigate between pages
- Repeated UI elements (status updates)
  - Angular implements these as *components*
- Different content, links, etc. displayed for each person

# A “large” client interface

- Loading lots of libraries can be slow and expensive
- So Angular supports sectioning parts of projects into distinct modules

# Angular modules

- Segment code into a library, similar to a JavaScript library
- A component only imports the modules it needs

# Angular modules

- By default, each Angular app has one module, `app.module.ts`
- But an app can create multiple modules to section off code
- `ng generate module [name]`
- Modules can *import* other modules
- Modules also *declare* which components they use
  - When you create a new component (`ng generate component [name]`), it automatically gets added to the declarations for the root module

# Angular modules

```
import { BrowserModule } from '@angular/platform-browser';
import { NgModule } from '@angular/core';
```

```
import { AppRoutingModule } from './app-routing.module';
import { AppComponent } from './app.component';
import { HelloComponent } from './hello/hello.component';
import { DayComponent } from './day/day.component';
```

```
@NgModule({
  declarations: [ ← Components used
    AppComponent,
    HelloComponent,
    DayComponent
  ],
  imports: [ ← Modules to import
    BrowserModule,
    AppRoutingModule
  ],
  providers: [],
  bootstrap: [AppComponent] ← The “root” component of the module
})
export class AppModule { }
```

# Angular modules

- `BrowserModule` is included by default
  - Required to run any app in the browser
- When creating an Angular project, can specify whether a *Routing* module should be created
  - Routing: defines what URIs to send to what endpoints
  - For Angular, defines what URIs to send to what components

# Angular routing

## app-routing.module.ts

```
import { NgModule } from '@angular/core';
import { Routes, RouterModule } from '@angular/router';
import { ArtistPageComponent } from '../pages/artist-page/artist-page.component';
import { TrackPageComponent } from '../pages/track-page/track-page.component';
import { AlbumPageComponent } from '../pages/album-page/album-page.component';
import { HomePageComponent } from '../pages/home-page/home-page.component';
```

```
const routes: Routes = [
  { path: 'artist/:id', component: ArtistPageComponent },
  { path: 'track/:id', component: TrackPageComponent },
  { path: 'album/:id', component: AlbumPageComponent },
  { path: '', component: HomePageComponent }
];
```

```
@NgModule({
  imports: [RouterModule.forRoot(routes)],
  exports: [RouterModule]
})
export class AppRoutingModule { }
```

◀ Listens for any endpoint  
artist/:id  
id can be retrieved in  
album-page.component.ts

# Retrieving route in a component

```
import { Component, OnInit } from '@angular/core';
import { ActivatedRoute } from '@angular/router';

@Component({
  selector: 'app-album-page',
  templateUrl: './album-page.component.html',
  styleUrls: ['./album-page.component.css']
})
export class AlbumPageComponent implements OnInit {

  constructor(private route: ActivatedRoute) { } ← “Injecting a service”

  ngOnInit() {
    var albumId = this.route.snapshot.paramMap.get('id'); ← Retrieve the id
    }                                     from the URI
  }
}
```

# Angular services

- Anything not associated with a specific view should be turned into a *service*
  - e.g., getting data from an API, parsing URIs for routing information
- Helps keep components lightweight
- Services can then be *injected* into a component (importing)
- To inject, import the service and retrieve it as a parameter in the constructor
- `ng generate service [name]`

# Angular services

```
import { Component, OnInit } from '@angular/core';  
import { ActivatedRoute } from '@angular/router';
```

 ← Importing a service

```
@Component({  
  selector: 'app-album-page',  
  templateUrl: './album-page.component.html',  
  styleUrls: ['./album-page.component.css']  
})  
export class AlbumPageComponent implements OnInit {
```

```
  constructor(private route: ActivatedRoute) { }
```

 ← Injecting it

```
  ngOnInit() {  
    var albumId = this.route.snapshot.paramMap.get('id');  
  }  
}
```

 ← Service can be referenced later

# Angular services

```
import { Injectable } from '@angular/core'; ← Defined as injectable
import { HttpClient, HttpHeaders } from '@angular/common/http';

@Injectable({
  providedIn: 'root' ← What module(s) can use this service
})
export class SpotifyService {
  baseUrl:string = 'http://localhost:8888';

  constructor(private http:HttpClient) { } ← HttpClient injected

  private sendRequestToExpress(endpoint:string) {
  }
}
```

# Import a custom service

```
import { Component, OnInit } from '@angular/core';
import { ActivatedRoute } from '@angular/router';
import { SpotifyService } from '../services/spotify.service';
```

Import service via file structure

```
@Component({
  selector: 'app-album-page',
  templateUrl: './album-page.component.html',
  styleUrls: ['./album-page.component.css']
})
export class AlbumPageComponent implements OnInit {

  constructor(private route: ActivatedRoute,
private spotifyService: SpotifyService) { }
```

Inject it like any other service

# Angular classes

- Plain-old classes can also be made in Angular
  - Any processing or munging you need to do, for example

- `ng generate class [name]`

```
export class Dataparser {  
  public constructor() {  
    console.log('Hello, world!');  
  }  
}
```

# Import a class

```
import { Component, OnInit, Input } from '@angular/core';  
import { Dataparser } from '../dataparser';
```

```
@Component({  
  selector: 'app-day',  
  templateUrl: './day.component.html',  
  styleUrls: ['./day.component.css']  
})  
export class DayComponent implements OnInit {  
  @Input() today:string;  
  
  days = ["Sunday", "Monday", "Tuesday", "Wednesday", "Thursday", "Friday", "Saturday"];  
  
  constructor() {  
    var data = new Dataparser();  
  }  
  
  ngOnInit() {  
  }  
}
```

↑  
Import class via file structure

↑  
Instantiate it like any other class

# Import a library

- Since Angular is in TypeScript, it can use any JavaScript or TypeScript library
- Install as normal with npm: `npm install [packagename]`
  - If you want TypeScript typings, don't forget to install `@types/[packagename]`

# Import a library

```
import * as chroma from 'chroma-js';
```

 Note: different syntax

```
export class Dataparser {
```

```
  constructor() {
```

```
    console.log(chroma('royalblue')); // '#4169e1'
```

```
  }
```

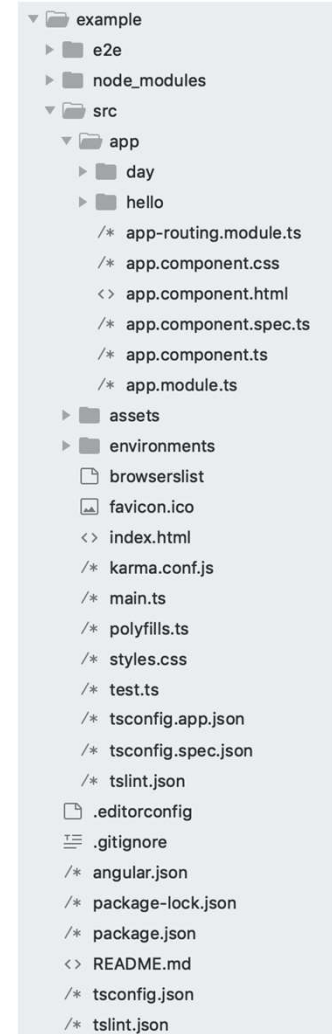

```
}
```

Can now be referenced

# Angular's file structure

- Angular projects generate a *lot* of files
  - There are about 75 in the starter code for A3
- Most are boilerplate

```
